- **Project Description:** Combine measurements of ozone and water vapor from recent satellite missions. Time period will extend from the mid 1980s to the present.

- **Applications:** Analysis of trends and variability, assessment of CCM simulations; ozone boundary conditions for global climate model simulations without interactive stratospheric chemistry; stratospheric water vapor boundary conditions for model sensitivity studies; inferences on trends and variability in stratospheric transport.

- **Users:** IPCC, Ozone Assessment (IOC) & SPARC/IGAC AC&C communities
Project Description

- We have 4 types of data sets for stratospheric ozone, and 2 for stratospheric water vapor.
- Ozone: there is an individual ozone profile compilation (this is referred to the BDBP), two monthly average versions (one involving computing shifts between satellites), and a regression fit.
- Water: there is a monthly average version with adjustments between satellites and one without.
- For model studies, filled versions (either via regression models or interpolation of anomalies) have been generated.
Why are we interested in stratospheric H₂O?

1) It impacts radiative processes including stratospheric temperature (potentially even impacting surface temperatures)

2) It impacts ozone chemistry in the stratosphere (via influence on OH chemistry, but also changing polar stratospheric cloud occurrence.)

3) From measurements of the mean distribution and variations we can infer something about temperatures and stratospheric motions.

4) Source to the mesosphere. Trends in stratospheric water + methane may ultimately result in trends in the mesosphere (and the interest here is potential trends in PMCs).
Why are we interested in stratospheric O$_3$?

1) Monitoring for ozone recovery.

2) It impacts radiative processes including stratospheric temperature (potentially even impacting surface temperatures and circulation).

3) From measurements of the mean distribution and variations we can infer something about temperatures and stratospheric motions.

*Water vapor compilation will be considered in the into the SPARC water vapor activity.*

*Ozone work will be considered in the The SI$^2$N Initiative on Past Changes in the Vertical Distribution of Ozone (SPARC, IOC, IGAC and NDACC)*
Ozone Database (#1)

- BDBP – “Binary Database of Profiles” (done with Greg Bodeker currently at Bodecker Scientific in New Zealand)
- Several different satellite-instruments and ozonesondes
- High resolution vertical profiles (so far mainly measurements by occultation instruments - solar or stellar - and sondes)
- Individual measurements saved on pre-defined database levels for pressure (70 levels), altitude (70 levels) and potential temperature (8 levels)
- Each profile is stored in each of the different database grids
- Ancillary data includes equivalent latitude
- Includes NO$_2$, H$_2$O, NO, CH$_4$, HCl, HF and aerosol extinction.
- QC’d and percentage uncertainty estimates included
Database structure

Version 1 hosted at: http://www.bodekerscientific.com/data/the-bdbp

We would like to have Version 2 hosted at NCDC
Ozone Database (#2)

• Vertically resolved and latitude/monthly gridded data set

• Based on the BDBP

• Used for subsequent representations of the data

Ozone Database (#3)

• Gap free latitude/time gridded version of the monthly averaged BDBP

• Multiple fitted versions provided using progressively more complex basis functions, solar, trends, qbo, annual, volcanic

Publication recently submitted to Earth System Science Data
Bodeker, Hassler, Young and Portmann, A vertically resolved, global, gap-free ozone database for assessing or constraining global climate model simulations. Currently available via ftp from Bodeker Scientific...we want to make it available at NCDC
Ozone Database (#4)

- Based on SAGE II&III, HALOE, UARS and Aura MLS
- Monthly averaged and latitudinally binned
- Comparisons are made with matching raw profiles to estimate adjustments in mixing ratio space
- Adjustments are a function of latitude and altitude
- Binning is done both in geographic and equivalent latitude space.
- A filled version is available, with interpolations in anomaly space.
- We intend to use the sonde measurements for independent verification of this filled data base.
Water Database (#1)

- This is constructed in the same manner as the ozone database (#4)

- Is currently available in beta version via ftp at NOAA ESRL CSD.

SWOOSH (Stratospheric Water and OzOne Satellite Homogenized), constructed by Sean Davis (CU/CIRESES and NOAA/ESRL).

Manuscript currently in preparation: Davis and Rosenlof, will be submitted to ACPD for the SI^2N Initiative special issue being organized by Neil Harris.
Problem: Stratospheric water vapor observations are not consistent in time

Stratospheric water vapor measurements have not been taken continuously at any one location or with any one technique for an extended period of time.
Ideally, we would like to be able to combine data sets to get an extended record, but first we need to assess whether different measurement systems are retrieving the same values at the same time/location.
Demonstration of stratospheric satellite measurement offsets

**Tropical tape recorder plot:** This shows the temporal evolution of tropical stratospheric water vapor over the past decade.
What sort of trends exist for stratospheric water vapor?

Note: trends are 0.5-1%/year, instruments differences are 5-10% or larger, so a simple combination will produce spurious trends.

Note: a trend of 10%/decade is equivalent to a 0.5 ppmv change

From Scherer et al, ACP 2008
Methodology for SWOOSH

1) Choose data sets with long continuous records, preferably global coverage, and some overlap in time/space.

2) Determine which data set to which to adjust.

3) Analyze the overlap period to determine adjustments that need to be made before combining data sets.

4) Establish the uncertainties for each part of the combined time series.

5) Determine some means of filling missing data (for cases where a complete data set is needed for model input.)
Approach

Data sets to consider:

1) SAGE II: 1985-2005
2) HALOE: 1991-2005
3) Aura MLS: 2004-present

To fill in gaps in polar regions; ACE (2004-present) can be used. Additionally, there are other shorter period satellite records.

Zonal average time series gridded with respect to equivalent latitude
Use of equivalent latitude allows greater latitudinal coverage.
How did we pick a basis instrument? (data shifted to match Aura MLS)

Use 2 methods to calculate entry value $H_2O$:
1) intercept for the water/methane relation at mid latitudes in the middle stratosphere
2) water value just above the tropical tropopause

GMD CH$_4$ surface value in 2007 was $\sim$1.775 ppmv

HALOE gives 3.1-3.3 for method 1; $\sim$3 for method 2
MLS gives 3.5-3.7 for method 1; $\sim$3.7 for method 2
MLS seems more consistent with the two methods of calculation.

MLS differences from Boulder frost point are smaller (by $\sim$0.5 ppmv) than HALOE differences.
We have therefore decided to compute the adjustment to MLS for the overlap period (2004 & 2005), and use those adjustments for the entire HALOE data set. This makes the assumption that there has been no drift in the HALOE measurements over the 1992-2005 time frame.
Database construction

Equivalent latitude, $\theta$
from MERRA

- SAGE-II (v6.2)
- UARS HALOE (v19)
- UARS MLS (v6)
- Aura MLS (v9)

**Quality control of profile data**
- Filter out bad data (all instruments)
  - Aerosol or cloud contamination, poor retrieval uncertainty
- Remove extreme outliers (SAGE only)
  - $O_3 > 15$ ppmv, or $H_2O > 25$ ppmv (and $p \leq 100$ hPa)
- Remove outliers using $3\sigma$ filter (SAGE only)
- MLS UTLS $H_2O$ adjustment
- Grid all data onto Aura MLS pressure grid

**Match profiles with Aura MLS**
- Match criteria: $\Delta x \leq 1000$ km, $\Delta t \leq 24$ hours, $\Delta$eqlat $\leq 7.0^\circ$
- Minimum equivalent latitude is used if multiple profiles

**Calculate offsets relative to Aura MLS**
- Defined as the mean of (Aura MLS -- "Other")
- Calculated in $10^\circ$ lat bins, at each pressure level

**Grid data**

Resolution:
- Monthly-mean (1984 – present)
- Zonal-mean (both $2.5^\circ$ and $10^\circ$ lat)
- 40 pressure levels (316 - 0.01 hPa) and 21 isentropic levels (300-650 K)
- Geographic and equivalent latitude grids for each variable

Information stored (lat, level, time):
- Mean, standard deviation, mean uncertainty, # of profiles in bin
  - For each satellite
  - Both uncorrected and corrected versions
- Combined -- weighted mean of all available measurements
- Combined, with anomaly-filling procedure
This allows for some geographical filling.

Classes of data sets desired:

- Tier 3: Use a regression model, fits include mean, annual cycle and any long-term change.
- Tier 2: Only include averages of measured values, adjusted if necessary.
- Tier 1: No adjustments.

Methodology for combining satellite water measurements into a zonally averaged gridded data set that can be used for quantifying variability and long-term changes in water vapor.

- MLS+HALOE comparisons:
  - MLS = 0.28 * HALOE + 3.45
  - MLS = 0.80 * HALOE + 1.84

Correlation without correction: 0.79
Correlation with correction: 0.91
Schedule & Issues

- **Project Status**: Our proposal has three objectives
  - 1) satellite record comparison during overlap periods: **done** for MLS/SAGE/HALOE water and ozone, **in progress** for other satellites (ie ACE, possibly MIPAS and balloons)
  - 2) use the water vapor and ozone time series to do trend and cycle analysis. In particular, we will examine features related to the change in tropical water vapor, temperatures and possible circulation changes that occurred at the end of 2000. **In progress**...a paper detailing anomalous NH polar ozone and relation to the tropics over the winter of 2010/2011
  - 3) analyze large-scale transport changes and radiative and climate impacts of observed changes and variability in stratospheric water vapor and ozone. **Done** for radiative forcing and ozone, **in progress** for radiative forcing and water vapor, **partially done** for transport changes.

- **State any risks or concerns**
  - We expect to complete the majority of what we set out to do by the end of FY13.

- **How can the CDR Program better assist you?**
  - When complete, we would like the data sets hosted by NCDC to increase use.
